Vectors

- Vectors are arrays of numerical values.
- ► Each numerical value is referred to as *coordinate*, *component*, *entry*, or *dimension*.
- The number of components is the vector dimensionality.
- e.g., a vector representation of a person: 25 years old (Age), making 30 dollars an hour (Salary), having 6 years of experience (Experience): [25, 30, 6].
- Vectors are special objects that can be added together and multiplied by scalars to produce another object of the same kind.

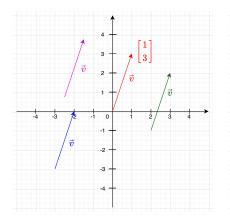

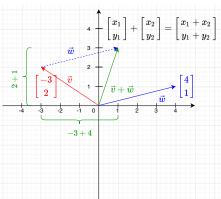

Geometric Vectors

- Geometric vectors are often visualized as a quantity that has a magnitude as well as a direction.
- ightharpoonup e.g., the velocity of a person moving at 1 meter/second in the eastern direction and 3 meters/second in the northern direction can be described as a directed line from the origin to (1,3).
- ▶ The **tail** of the vector is at the origin. The **head** is at (1,3).
- Geometric vectors can have arbitrary tails.
- lacktriangle Two geometric vectors can be added, such that x+y=z is another geometric vector.
- Multiplication by a scalar $\lambda x, \lambda \in \mathbb{R}$, is also a geometric vector.

Vectors

Vectors

- Polynomials are vectors. Adding two polynomials results in another polynomial. Multiplied by a scalar, the result is also a polynomial.
- Audio signals are also vectors. Addition of two audio signals and scalar multiplication result in new audio signals.
- ightharpoonup Elements of \mathbb{R}^n (tuples of n real numbers) are vectors. For example,

$$\boldsymbol{a} = \begin{bmatrix} 6\\14\\-3 \end{bmatrix} \in \mathbb{R}^3$$

is a triplet of numbers. Adding two vectors ${m a}, {m b} \in \mathbb{R}^n$ component-wise results in another vectors ${m a} + {m b} = {m c} \in \mathbb{R}^n$. Multiplying ${m a} \in \mathbb{R}^n$ by $\lambda \in \mathbb{R}$ results in a scaled vector $\lambda {m a} \in \mathbb{R}^n$.

- ▶ Vector of the same dimensionality can be added or subtracted.
- Consider two d-dimensional vectors:

$$\boldsymbol{x} + \boldsymbol{y} = \begin{bmatrix} x_1 \\ \dots \\ x_d \end{bmatrix} + \begin{bmatrix} y_1 \\ \dots \\ y_d \end{bmatrix} = \begin{bmatrix} x_1 + y_1 \\ \dots \\ x_d + y_d \end{bmatrix} \quad \boldsymbol{x} - \boldsymbol{y} = \begin{bmatrix} x_1 \\ \dots \\ x_d \end{bmatrix} - \begin{bmatrix} y_1 \\ \dots \\ y_d \end{bmatrix} = \begin{bmatrix} x_1 - y_1 \\ \dots \\ x_d - y_d \end{bmatrix}$$

▶ Vector addition is commutative: x + y = y + x.

lacktriangle A vector $oldsymbol{x} \in \mathbb{R}^d$ can be scaled by a factor $a \in \mathbb{R}$ as follows

$$\mathbf{v} = a\mathbf{x} = a \begin{bmatrix} x_1 \\ \dots \\ x_d \end{bmatrix} = \begin{bmatrix} ax_1 \\ \dots \\ ax_d \end{bmatrix}$$

 Scalar multiplication operation scales the "length" of the vector, but does not change the "direction" (i.e., relative values of different components)

▶ The **dot product** between two vectors $x, y \in \mathbb{R}^d$ is the sum of the element-wise multiplication of their individual components.

$$\boldsymbol{x} \cdot \boldsymbol{y} = \sum_{i=1}^{d} x_i y_i$$

▶ The dot product is commutative:

$$\boldsymbol{x} \cdot \boldsymbol{y} = \sum_{i=1}^{d} x_i y_i = \sum_{i=1}^{d} y_i x_i = \boldsymbol{y} \cdot \boldsymbol{x}$$

The dot product is distributive:

$$x \cdot (y + z) = x \cdot y + x \cdot z$$

▶ The dot product of a vector with itself produces the squared Euclidean norm. The norm defines the vector length and is denoted by $\|\cdot\|$:

$$||x||^2 = \boldsymbol{x} \cdot \boldsymbol{x} = \sum_{i=1}^d x_i^2$$

▶ The Euclidean norm of $x \in \mathbb{R}^d$ is defined as

$$||x||_2 = \sqrt{\sum_{i=1}^d x_i^2} = \sqrt{\boldsymbol{x} \cdot \boldsymbol{x}}$$

and computes the Euclidean distance of x from the origin.

▶ The Euclidean norm is also known as the L_2 -norm.

A generalization of the Euclidean norm is the L_p -norm, denoted by $\|\cdot\|_p$:

$$||x||_p = \left(\sum_{i=1}^d |x_i|^p\right)^{(1/p)}$$

where p is a positive value.

lacktriangle When p=1, we have the Manhattan norm, or the L_1 -norm.

Vectors can be normalized to unit length by dividing them with their norm:

$$oldsymbol{x}' = rac{oldsymbol{x}}{\|oldsymbol{x}\|} = rac{oldsymbol{x}}{\sqrt{oldsymbol{x}\cdotoldsymbol{x}}}$$

- The resulting vector is a unit vector.
- lacktriangle The squared Euclidean distance $x,y\in\mathbb{R}^d$ can be shown to be the dot product of x - y with itself:

$$\|x - y\|^2 = (x - y) \cdot (x - y) = \sum_{i=1}^{d} (x_i - y_i)^2$$

Cauchy-Schwarz Inequality: the dot product between a pair of vectors is bounded above by the product of their lengths.

$$\left| \sum_{i=1}^{d} x_i y_i \right| = |\boldsymbol{x} \cdot \boldsymbol{y}| \le \|\boldsymbol{x}\| \|\boldsymbol{y}\|$$

Triangle Inequality: Consider the triangle formed by the origin, x, and y, the side length $\|x-y\|$ is no greater than the sum $\|x\|+\|y\|$ of the other two sides.

- Consider the triangle created by the origin, x, and y. Find the angle θ between x and y.
- The side lengths of this triangle are: a = ||x||, b = ||y||, and c = ||x y||. Using the cosine law, we have:

$$\cos(\theta) = \frac{a^2 + b^2 - c^2}{2ab} = \frac{\|\boldsymbol{x}\|^2 + \|\boldsymbol{y}\|^2 - \|\boldsymbol{x} - \boldsymbol{y}\|^2}{2\|\boldsymbol{x}\|\|\boldsymbol{y}\|}$$
$$= \frac{\|\boldsymbol{x}\|^2 + \|\boldsymbol{y}\|^2 - (\boldsymbol{x} - \boldsymbol{y}) \cdot (\boldsymbol{x} - \boldsymbol{y})}{2\|\boldsymbol{x}\|\|\boldsymbol{y}\|}$$
$$= \frac{\boldsymbol{x} \cdot \boldsymbol{y}}{\|\boldsymbol{x}\|\|\boldsymbol{y}\|}$$

- Two vectors are orthogonal if their dot product is 0.
- ▶ The vector 0 is considered orthogonal to every vector.

Matrices

Definition

With $m,n\in\mathbb{N}$, a real-valued (m,n) matrix \boldsymbol{A} is an $m\cdot n$ -tuple of elements $a_{ij},i=1,\ldots,m,j=1,\ldots,n$, which is ordered according to a rectangular scheme consisting of m rows and n columns:

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix}, \quad a_{ij} \in \mathbb{R}$$

 $\mathbb{R}^{m \times n}$ is the set of all real-valued (m, n)-matrices.

 $A \in \mathbb{R}^{m \times n}$ can also be represented as $a \in \mathbb{R}^{mn}$ by stacking all n columns of the matrix into a long vector.

Matrices

- ► A matrix has the same number of rows as columns is a **square** matrix. Otherwise, it is a **rectangular** matrix.
- A matrix having more rows than columns is referred to as *tall*, while a matrix having more columns than rows is referred to as *wide* or *fat*.
- A scalar can be considered as a 1×1 "matrix".
- ▶ A d-dimensional vector can be considered a $1 \times d$ matrix when it is treated as a **row vector**.
- ▶ A d-dimensional vector can be considered a $d \times 1$ matrix when it is treated as a **column vector**.
- By defaults, vectors are assumed to be column vectors.

Matrix-Vector Multiplication

$$\begin{bmatrix} \cos 90^{\circ} & \sin 90^{\circ} \\ -\sin 90^{\circ} & \cos 90^{\circ} \end{bmatrix} \begin{bmatrix} \alpha_{1} \\ \alpha_{2} \end{bmatrix} = \begin{bmatrix} \Omega_{2} & \Omega_{2} \\ \Omega_{2} \end{bmatrix}$$

Matrix-Vector Multiplication Ax

ightharpoonup Multiply A times x using rows of A.

$$\begin{bmatrix} 2 & 3 \\ 2 & 4 \\ 3 & 7 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 2x_1 + 3x_2 \\ 2x_1 + 4x_2 \\ 3x_1 + 7x_2 \end{bmatrix} = \begin{bmatrix} \boldsymbol{a}_1^* \boldsymbol{x} \\ \boldsymbol{a}_2^* \boldsymbol{x} \\ \boldsymbol{a}_3^* \boldsymbol{x} \end{bmatrix}$$

Ax = dot products of rows of A with x.

▶ Multiply A times x using columns of A.

$$\begin{bmatrix} 2 & 3 \\ 2 & 4 \\ 3 & 7 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = x_1 \begin{bmatrix} 2 \\ 2 \\ 3 \end{bmatrix} + x_2 \begin{bmatrix} 3 \\ 4 \\ 7 \end{bmatrix} = x_1 \boldsymbol{a}_1 + x_2 \boldsymbol{a}_2$$

Ax = combination of columns of a_1 , a_2 (of A) scaled by scalars x_1 , x_2 respectively.

Linear Combinations of Columns

Ax

Ax is a linear combination of the columns of A.

$$\begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} = x_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{m1} \end{bmatrix} + x_2 \begin{bmatrix} a_{12} \\ a_{22} \\ \vdots \\ a_{m2} \end{bmatrix} + \dots + x_n \begin{bmatrix} a_{1n} \\ a_{2n} \\ \vdots \\ a_{mn} \end{bmatrix}$$

$$A\mathbf{x} = x_1 \mathbf{a}_1 + x_2 \mathbf{a}_2 + \dots + x_n \mathbf{a}_n$$

Column space of
$$A = \mathbf{C}(A) = \text{all vectors } Ax$$

= all linear combinations of the column

Column Space of A

$$A\boldsymbol{x} = \begin{bmatrix} 2 & 3 \\ 2 & 4 \\ 3 & 7 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = x_1 \begin{bmatrix} 2 \\ 2 \\ 3 \end{bmatrix} + x_2 \begin{bmatrix} 3 \\ 4 \\ 7 \end{bmatrix}$$

- **Each** Ax is a vector in the \mathbb{R}^3 space.
- All combinations $Ax = x_1a_1 + x_2a_2$ produce what part of \mathbb{R}^3 ?
- Answer: a **plane**, containing:
 - the line of all vectors $x_1 \mathbf{a}_1$,
 - the line of all vectors $x_2 a_2$,
 - the sum of any vector on one line + any vector on the other line, filling out an **infinite plane** containing the two lines, but not the whole \mathbb{R}^3 .

Definition

The combinations of the columns fill out the column space of A.

Column Space of A

$$A\boldsymbol{x} = \begin{bmatrix} 2 & 3 \\ 2 & 4 \\ 3 & 7 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = x_1 \begin{bmatrix} 2 \\ 2 \\ 3 \end{bmatrix} + x_2 \begin{bmatrix} 3 \\ 4 \\ 7 \end{bmatrix}$$

- ightharpoonup C(A) is plane.
- ▶ The plane includes (0,0,0), produced when $x_1 = x_2 = 0$.
- The plane includes $(5,6,10) = \mathbf{a}_1 + \mathbf{a}_2$ and $(-1,-2,-4) = \mathbf{a}_1 \mathbf{a}_2$. Every combination $x_1\mathbf{a}_1 + x_2\mathbf{a}_2$ is in $\mathbf{C}(A)$.
- ► The probability the plane does not include a random point **rand**(3,1)? Which points are in the plane?

Ax = b

b is in C(A) exactly when Ax = b has a solution x. x shows how to express b as a combination of the columns of A.

Column Space of A

 $\mathbf{b} = (1, 1, 1)$ is not in $\mathbf{C}(A)$ because

$$A oldsymbol{x} = egin{bmatrix} 2 & 3 \\ 2 & 4 \\ 3 & 7 \end{bmatrix} egin{bmatrix} x_1 \\ x_2 \end{bmatrix} = egin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$
 is unsolvable.

What is the column space of A₂?

$$\begin{bmatrix} 2 & 3 & 5 \\ 2 & 4 & 6 \\ 3 & 7 & 10 \end{bmatrix}$$

- $a_3 = a_1 + a_2$, is already in C(A), the plane of a_1 and a_2 .
- $\begin{bmatrix} 2 & 3 & 5 \\ 2 & 4 & 6 \\ 3 & 7 & 10 \end{bmatrix}$ Including this **dependent** column does not go beyond $\mathbf{C}(A)$.

 - ▶ What is the column space of A₃?

$$\begin{bmatrix} 2 & 3 & 1 \\ 2 & 4 & 1 \\ 3 & 7 & 1 \end{bmatrix}$$

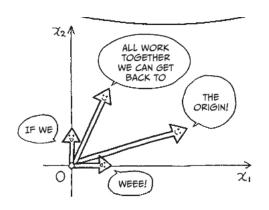

- $a_3 = (1, 1, 1)$ is not in the plane C(A).
- $\begin{bmatrix} 2 & 3 & 1 \\ 2 & 4 & 1 \\ 3 & 7 & 1 \end{bmatrix}$ Visualize the xy-plane and a third vector (x_3, y_3, z_3) out of the plane (meaning that $z_3 \neq 0$).
 - $C(A_3)=\mathbb{R}^3$.

Column Spaces of \mathbb{R}^3

- ▶ Subspaces of \mathbb{R}^3 :
 - The zero vector (0,0,0).
 - A line of all vectors $x_1 a_1$.
 - A plane of all vectors $x_1 a_1 + x_2 a_2$.
 - The whole \mathbb{R}^3 with all vectors $x_1 \mathbf{a}_1 + x_2 \mathbf{a}_2 + x_3 \mathbf{a}_3$.
- Vectors a_1, a_2, a_3 need to be **independent**. The only combination that gives the zero vector is $0a_1 + 0a_2 + 0a_3$.
- ► The zero vector is in every subspace.

Linear Dependence

LINEAR DEPENDENCE

³https://mathsci2.appstate.edu/ sjg/class/2240/hf14.html

Independent Columns, Basis, and Ranks of A

Definition

A **basis** for a subspace is a full set of independent vectors: All vectors in the space are combinations of the basis vector.

Create a matrix C whose columns come directly from A:

- ▶ If column 1 of A is not all zero, put it into C.
- ▶ If column 2 of A is not a multiple of column 1, put it into C.
- ► If column 3 of A is not a combination of columns 1 and 2, put it into C. Continue.
- At the end, C will have r columns $(r \le n)$. They are independent columns, and they are a "basis" for the column space $\mathbf{C}(A)$.

Independent Columns, Basis, and Ranks of A

$$\begin{split} &\text{If } A = \begin{bmatrix} 1 & 3 & 8 \\ 1 & 2 & 6 \\ 0 & 1 & 2 \end{bmatrix} \text{ then } C = \begin{bmatrix} 1 & 3 \\ 1 & 2 \\ 0 & 1 \end{bmatrix} \quad \begin{matrix} n = 3 \text{ columns in } A \\ r = 2 \text{ columns in } C \\ \end{split} \\ &\text{If } A = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & 0 & 6 \end{bmatrix} \text{ then } C = A \quad \quad \begin{matrix} n = 3 \text{ columns in } A \\ r = 3 \text{ columns in } C \\ \end{split} \\ &\text{If } A = \begin{bmatrix} 1 & 2 & 5 \\ 1 & 2 & 5 \\ 1 & 2 & 5 \\ 1 & 2 & 5 \\ \end{matrix} \\ \text{ then } C = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} \quad \begin{matrix} n = 3 \text{ columns in } A \\ r = 1 \text{ columns in } C \\ \end{matrix}$$

- ▶ The number *r* counts independent columns.
- ▶ It is the "dimension" of the column space of A and C (same space).

Definition

The rank of a matrix is the dimension of its column space.

Rank Factorization A = CR

- ▶ The matrix C connects to A by a third matrix R: A = CR.
- $A \in \mathbb{R}^{m \times n}, C \in \mathbb{R}^{m \times r}, R \in \mathbb{R}^{r \times n}$

$$A = \begin{bmatrix} 1 & 3 & 8 \\ 1 & 2 & 6 \\ 0 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 3 \\ 1 & 2 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & 2 \end{bmatrix} = CR$$

- C multiplies the first column of R produces column 1 of A.
- C multiplies the second column of R produces column 2 of A.
- C multiplies the third column of R produces column 3 of A.
- ▶ Combinations of the columns of C produce the columns of A \longrightarrow Put the right numbers in R.

Definition

 $R = \mathbf{rref}(A) = \text{row-reduced echelon form of } A.$

Rank Factorization A = CR

$$A = \begin{bmatrix} 1 & 3 & 8 \\ 1 & 2 & 6 \\ 0 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 3 \\ 1 & 2 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & 2 \end{bmatrix} = CR$$

- ▶ The matrix R has r = 2 rows r_1^* , r_2^* .
- ▶ Multiply row 1 of C with R, we get $r_1^* + 3r_2^* \rightarrow \text{row 1 of } A$.
- ▶ Multiply row 2 of C with R, we get $r_1^* + 2r_2^* \rightarrow$ row 2 of A.
- ▶ Multiply row 3 of C with R, we get $0r_1^* + 1r_2^* \rightarrow$ row 3 of A.
- ▶ R has independent rows: No row is a combination of the other rows. Hint: Look at the zeros and ones in R - the identity matrix I in R.
- ▶ The rows of *R* are a **basis for the row space** of *A*.
- Notation: The row space of matrix $A = \mathbf{C}(A^{\top})$.

Rank Factorization A = CR

- **1** The r columns of C are independent (by their construction).
- 2 Every column of A is a combination of those r columns of C (because A = CR).
- **3** The r rows of R are independent (they contain the matrix I_r).
- Every row of A is a combination of those r rows of R (because A=CR).

Key facts:

- ▶ The r columns of C is a **basis** for C(A): dimension r.
- ▶ The r rows of R is a **basis** for $C(A^T)$: dimension r.

Notice

The number of independent columns = The number of independent rows. The column space and row space of A both have dimension r.

The column rank of A =The row rank of A.

Q&A

Question: If an $n \times n$ matrix A has n independent columns, then

C = ?, R = ?

Answer: C = A, R = I.

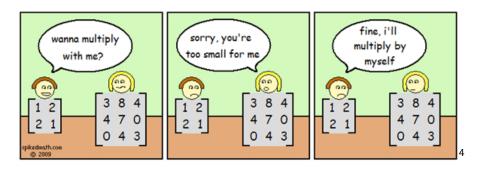

Table of Contents

Matrix-Matrix Multiplication AB

⁴https://mathsci2.appstate.edu/ sjg/class/2240/hf14.html

Compute AB by Inner Products

Inner products (rows times columns) produce each of the numbers in AB = C:

$$\begin{bmatrix} \cdot & \cdot & \cdot \\ a_{21} & a_{22} & a_{23} \\ \cdot & \cdot & \cdot \end{bmatrix} \begin{bmatrix} \cdot & \cdot & b_{13} \\ \cdot & \cdot & b_{23} \\ \cdot & \cdot & b_{33} \end{bmatrix} = \begin{bmatrix} \cdot & \cdot & \cdot \\ \cdot & \cdot & c_{23} \\ \cdot & \cdot & \cdot \end{bmatrix}$$

 $ightharpoonup c_{i,i} = (\text{row } i \text{ of } A) \cdot (\text{column } j \text{ of } B)$

$$c_{ij} = a_{i1}b_{1j} + a_{i2}b_{2j} + \dots + a_{in}b_{nj} = \sum_{k=1}^{n} a_{ik}b_{kj} = \boldsymbol{a}_{i}^{*}\boldsymbol{b}_{j}$$

Rank-1 Matrix

▶ Outer products (columns times rows) produce rank one matrices.

$$m{u}m{v}^{ op} = egin{bmatrix} 2 \\ 2 \\ 1 \end{bmatrix} m{\begin{bmatrix}} 3 & 4 & 6 \end{bmatrix} = m{\begin{bmatrix}} 6 & 8 & 12 \\ 6 & 8 & 12 \\ 3 & 4 & 6 \end{bmatrix}$$

- An $m \times 1$ matrix (a column \boldsymbol{u}) times a $1 \times p$ matrix (a row \boldsymbol{v}^{\top}) gives an $m \times p$ matrix.
- lacktriangle All columns of uv^{\top} are multiples of u.
- lacktriangle All rows of $uv^{ op}$ are multiples of $v^{ op}$.
- ▶ The column space of uv^{\top} is the line through u.
- ▶ The row space of uv^{\top} is the line through v.
- lacktriangle All non-zero matrices $uv^{ op}$ have rank one.

AB = Sum of Rank-1 Matrices

▶ The product AB is the sum of columns a_k times rows b_k^* .

$$AB = \begin{bmatrix} | & & | \\ \boldsymbol{a}_1 & \dots & \boldsymbol{a}_n \\ | & & | \end{bmatrix} \begin{bmatrix} - & \boldsymbol{b}_1^* & - \\ & \vdots & \\ - & \boldsymbol{b}_n^* & - \end{bmatrix} = \boldsymbol{a}_1 \boldsymbol{b}_1^* + \boldsymbol{a}_2 \boldsymbol{b}_2^* + \dots + \boldsymbol{a}_n \boldsymbol{b}_n^*$$

Example:

$$\begin{bmatrix} 1 & 0 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} 2 & 4 \\ 0 & 5 \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \end{bmatrix} \begin{bmatrix} 2 & 4 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \begin{bmatrix} 0 & 5 \end{bmatrix} = \begin{bmatrix} 2 & 4 \\ 6 & 12 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 5 \end{bmatrix} = \begin{bmatrix} 2 & 4 \\ 6 & 17 \end{bmatrix}$$

Insight from Column times Row

- Looking for the important part of a matrix A.
- ▶ Factor A into CR and look at the pieces $c_k r_k^*$ of A = CR.
- ▶ Factoring A into CR is the reverse of multiplying CR = A.
- ▶ The inside information about A is not visible until A is factored.

Important Factorizations

- \bullet A = LU: elimination
- $\mathbf{Q} A = QR$: orthogonalization
- \bullet $S = Q\Lambda Q^{\top}$: eigenvalues and orthonormal eigenvectors
- \bullet $A = X\Lambda X^{-1}$: diagonalization
- **3** $A = U\Sigma V^{\top}$: Singular Value Decomposition (SVD)

Inverse Matrices

▶ The square matrix A is invertible if there exists a matrix A^{-1} that

$$A^{-1}A = I \text{ and } AA^{-1} = I$$

▶ The matrix A cannot have two different inverses. Suppose BA = I and also AC = I. Then B = C.

$$B(AC) = (BA)C$$
 gives $BI = IC$ or $B = C$.

- ▶ If A is invertible, the one and only solution to Ax = b is $x = A^{-1}b$.
- ▶ If Ax = 0 for a nonzero vector x, then A has no inverse.
- \blacktriangleright If A and B are invertible then so is AB. The inverse of AB is

$$(AB)^{-1} = B^{-1}A^{-1}$$

Table of Contents

- 3 The Four Fundamental Subspaces of A: $\mathbf{C}(A)$, $\mathbf{C}(A^{\top})$, $\mathbf{N}(A)$, $\mathbf{N}(A^{\top})$
- 4 Elimination and A=LU
- 5 Orthogonal Matrices, Subspaces, and Projections

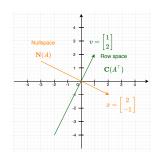

Example 1

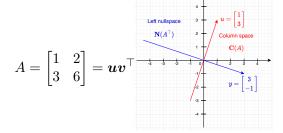

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 6 \end{bmatrix} = \boldsymbol{u}\boldsymbol{v}^\top$$

- $lackbox{\sf Column}$ Space $lackbox{\sf C}(A)$ is the line through $m{u}=egin{bmatrix}1\\3\end{bmatrix}$.
- $lackbox{\sf Row}$ Row space ${f C}(A^{ op})$ is the line through $m v=egin{bmatrix}1\\2\end{bmatrix}$.
- Nullspace $\mathbf{N}(A)$ is the line through $x = \begin{bmatrix} 2 \\ -1 \end{bmatrix}$. $Ax = \mathbf{0}$.
- Left nullspace $\mathbf{N}(A^{\top})$ is the line through $\mathbf{y} = \begin{bmatrix} 3 \\ -1 \end{bmatrix}$. $A^{\top}\mathbf{y} = \mathbf{0}$.

Example 1

Definition

The column space $\mathbf{C}(A)$ contains all combinations of the columns of A.

The row space $C(A^{\top})$ contains all combinations of the columns of A^{\top} .

The nullspace N(A) contains all solutions x to Ax = 0.

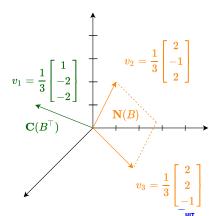

The left nullspace $\mathbf{N}(A^{\top})$ contains all solutions y to $A^{\top}y = 0$.

Example 2

$$B = \begin{bmatrix} 1 & -2 & -2 \\ 3 & -6 & -6 \end{bmatrix}$$

- The row space $C(B^{\top})$ is the infinite line through $v_1 = \frac{1}{3}(1, -2, -2)$.
- ▶ Bx = 0 has solutions $x_1 = (2, 1, 0)$ and $x_2 = (2, 0, 1)$.
- **x**₁ and x_2 are in the same plane with $v_2 = \frac{1}{3}(2, -1, 2)$ and $v_3 = \frac{1}{3}(2, 2, -1)$.
- ► The nullspace N(B) has an orthonormal basis v_2 and v_3 , is the infinite plane of v_2 and v_3 .
- $ightharpoonup v_1, v_2, v_3$: an orthonormal basis for \mathbb{R}^3 .

Subspaces of A

If
$$Ax = \mathbf{0}$$
 then $\begin{bmatrix} \operatorname{row} & 1 \\ \vdots \\ \operatorname{row} & m \end{bmatrix} \begin{bmatrix} x \\ \end{bmatrix} = \begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix}$

- ightharpoonup x is orthogonal to every row of A.
- Every x in the nullspace of A is orthogonal to the row space of A.
- Every \boldsymbol{y} in the nullspace of A^{\top} is orthogonal to the column space of A.

$$\begin{array}{cccc} \mathbf{N}(A) \perp \mathbf{C}(A^\top) & \mathbf{N}(A^\top) \bot \ \mathbf{C}(A) \\ \text{Dimensions} & n-r & r & m-r & r \end{array}$$

lacktriangle Two orthogonal subspaces. The dimensions add to n and to m.

Ax = b by Elimination

The usual order:

- Column 1.
 - Row 1 is the first pivot row.
 - Multiply row 1 by numbers $l_{21}, l_{31}, \ldots, l_{n1}$ and subtract from rows $2, 3, \ldots, n$ of A respectively.

Multipliers
$$l_{21}=\frac{a_{21}}{a_{11}}$$
 $l_{31}=\frac{a_{31}}{a_{11}}$... $l_{n1}=\frac{a_{n1}}{a_{11}}$

$$\begin{bmatrix} A \mid \boldsymbol{b} \end{bmatrix} = \begin{bmatrix} 2 & 1 & -1 & 2 \mid 5 \\ 4 & 5 & -3 & 6 \mid 9 \\ -2 & 5 & -2 & 6 \mid 4 \\ 4 & 11 & -4 & 8 \mid 2 \end{bmatrix} \rightarrow \begin{bmatrix} 2 & 1 & -1 & 2 \mid 5 \\ 0 & 3 & -1 & 2 \mid -1 \\ 0 & 6 & -3 & 8 \mid 9 \\ 0 & 9 & -2 & 4 \mid -8 \end{bmatrix}$$

$Aoldsymbol{x} = oldsymbol{b}$ by Elimination

The usual order:

- Column 2.
 - The new row 2 is the second pivot row.
 - Multiply row 2 by numbers $l_{32}, l_{42}, \ldots, l_{n2}$ and subtract from rows $3, 4, \ldots, n$ of A respectively.

Multipliers
$$l_{32}=\frac{a_{32}}{a_{22}}$$
 $l_{42}=\frac{a_{42}}{a_{22}}$... $l_{n2}=\frac{a_{n2}}{a_{22}}$

$$\begin{bmatrix} 2 & 1 & -1 & 2 & 5 \\ 0 & 3 & -1 & 2 & -1 \\ 0 & 6 & -3 & 8 & 9 \\ 0 & 9 & -2 & 4 & -8 \end{bmatrix} \rightarrow \begin{bmatrix} 2 & 1 & -1 & 2 & 5 \\ 0 & 3 & -1 & 2 & -1 \\ 0 & 0 & -1 & 4 & 11 \\ 0 & 0 & 1 & -2 & -5 \end{bmatrix}$$

Ax = b by Elimination

The usual order:

- ► Column 3.
 - The new row 3 is the third pivot row.
 - Multiply row 3 by numbers $l_{43}, l_{53}, \ldots, l_{n3}$ and subtract from rows $4, 5, \ldots, n$ of A respectively.

Multipliers
$$l_{43}=\frac{a_{43}}{a_{33}}$$
 $l_{53}=\frac{a_{53}}{a_{33}}$... $l_{n3}=\frac{a_{n3}}{a_{33}}$

$$\begin{bmatrix} 2 & 1 & -1 & 2 & 5 \\ 0 & 3 & -1 & 2 & -1 \\ 0 & 0 & -1 & 4 & 11 \\ 0 & 0 & 1 & -2 & -5 \end{bmatrix} \rightarrow \begin{bmatrix} 2 & 1 & -1 & 2 & 5 \\ 0 & 3 & -1 & 2 & -1 \\ 0 & 0 & -1 & 4 & 11 \\ 0 & 0 & 0 & 2 & 6 \end{bmatrix} = \begin{bmatrix} U \mid \mathbf{c} \end{bmatrix}$$

Columns 3 to n: Eliminating on A until obtaining the upper triangular U: n pivots on its diagonal.

$Aoldsymbol{x} = oldsymbol{b}$ by Elimination

$$2x_1 + x_2 - x_3 + 2x_4 = 5$$
$$3x_2 - x_3 + 2x_4 = -1$$
$$-x_3 + 4x_4 = 11$$
$$2x_4 = 6$$

By back substitution, we get

$$x_4 = 3$$
, $x_3 = 1$, $x_2 = -2$, $x_1 = 1$

Lower Triangular L and Upper Triangular U

lacktriangle Elimination on $Aoldsymbol{x}=oldsymbol{b}$ produces the upper triangular matrix

$$U = \begin{bmatrix} 2 & 1 & -1 & 2 \\ 0 & 3 & -1 & 2 \\ 0 & 0 & -1 & 4 \\ 0 & 0 & 0 & 2 \end{bmatrix}$$

▶ and the lower triangular matrix

$$L = \begin{bmatrix} \mathbf{1} & 0 & 0 & 0 \\ l_{21} & \mathbf{1} & 0 & 0 \\ l_{31} & l_{32} & \mathbf{1} & 0 \\ l_{41} & l_{42} & l_{43} & \mathbf{1} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 2 & 1 & 0 & 0 \\ -1 & 2 & 1 & 0 \\ 2 & 3 & -1 & 1 \end{bmatrix}$$

ightharpoonup Elimination factors A into a lower triangular L times an upper triangular U.

$$A = LU$$

The Factorization A = LU

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ l_{21} & 1 & 0 & 0 \\ l_{31} & l_{32} & 1 & 0 \\ l_{41} & l_{42} & l_{43} & 1 \end{bmatrix} \begin{bmatrix} \text{pivot row 1} \\ \text{pivot row 2} \\ \text{pivot row 3} \\ \text{pivot row 4} \end{bmatrix} = \begin{bmatrix} 2 & 1 & -1 & 2 \\ 4 & 5 & -3 & 6 \\ -2 & 5 & -2 & 6 \\ 4 & 11 & -4 & 8 \end{bmatrix}$$

$$= \begin{bmatrix} 1 \\ l_{21} \\ l_{31} \\ l_{41} \end{bmatrix} \begin{bmatrix} \text{pivot row 1} \end{bmatrix} + \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \end{bmatrix}$$

$$= \begin{bmatrix} 1 \\ 2 \\ -1 \\ 2 \end{bmatrix} \begin{bmatrix} 2 & 1 & -1 & 2 \end{bmatrix} + \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & x & x & x \\ 0 & x & x & x \\ 0 & x & x & x \end{bmatrix}$$

$$= \begin{bmatrix} 2 & 1 & -1 & 2 \\ 4 & 2 & -2 & 4 \\ -2 & -1 & 1 & -2 \\ 4 & 2 & 0 & 2 & 4 \end{bmatrix} + \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 3 & -1 & 2 \\ 0 & 6 & -3 & 8 \\ 0 & 0 & 2 & 2 \end{bmatrix}$$

The first step reduces the 4×4 problem to a 3×3 problem by removing $l_1 u_1^*$.

The Factorization A = LU

The second step reduces the 3×3 problem to a 2×2 problem by removing $l_2 u_2^*$

The Factorization A = LU

The third step reduces the 2×2 problem to a single number by removing ${m l}_3 {m u}_3^*$.

Elimination and A = LU

- ▶ Start from $\begin{bmatrix} A & \boldsymbol{b} \end{bmatrix} = \begin{bmatrix} LU & \boldsymbol{b} \end{bmatrix}$.
- ▶ Elimination on Ax = b produces the equation Ux = c that are ready for back substitution.
- $ightharpoonup A = LU = \sum l_i u_i^* = \text{sum of rank one matrices}.$

Table of Contents

- Matrix-Vector Multiplication Aa
- 2 Matrix-Matrix Multiplication AB
- 3 The Four Fundamental Subspaces of A: $\mathbf{C}(A)$, $\mathbf{C}(A^{\top})$, $\mathbf{N}(A)$, $\mathbf{N}(A^{\top})$
- 4 Elimination and A=LU
- 5 Orthogonal Matrices, Subspaces, and Projections

Orthogonality

- ightharpoonup Orthogonal \sim perpendicular.
- lacktriangle Orthogonal vectors $oldsymbol{x}$ and $oldsymbol{y}$:

$$\boldsymbol{x}^{\top}\boldsymbol{y} = x_1y_1 + x_2y_2 + \dots + x_ny_n = 0$$

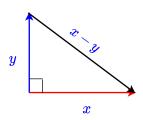

Law of Cosines: θ is the angle between x and y:

$$\|x - y\|^2 = \|x\|^2 + \|y\|^2 - 2\|x\|\|y\|\cos\theta$$

Orthogonal vectors have $\cos \theta = 0$.

Pythagoras Law:

$$\begin{aligned} \|\boldsymbol{x} - \boldsymbol{y}\|^2 &= \|\boldsymbol{x}\|^2 + \|\boldsymbol{y}\|^2 \\ (\boldsymbol{x} - \boldsymbol{y})^\top (\boldsymbol{x} - \boldsymbol{y}) &= \boldsymbol{x}^\top \boldsymbol{x} + \boldsymbol{y}^\top \boldsymbol{y} \\ \boldsymbol{x}^\top \boldsymbol{x} + \boldsymbol{y}^\top \boldsymbol{y} - \boldsymbol{x}^\top \boldsymbol{y} - \boldsymbol{y}^\top \boldsymbol{x} &= \boldsymbol{x}^\top \boldsymbol{x} + \boldsymbol{y}^\top \boldsymbol{y} \\ \boldsymbol{x}^\top \boldsymbol{y} &= 0 \end{aligned}$$

Orthogonal Basis

- $lackbox{ extbf{V}}$ Orthogonal basis for a subspace: Every pair of basis vectors has $oldsymbol{v}_i^ op oldsymbol{v}_j = 0$
- ▶ Orthonormal basis: Orthogonal basis of unit vectors: Every ${m v}_i^{\top}{m v}_i = 1$ (length 1).
- From orthogonal to orthonormal, divide every basis vector v_i by its length $\|v_i\|$.
- lacktriangle The standard basis is orthogonal (and orthonormal) in \mathbb{R}^n :

Standard basis
$$\pmb{i}, \pmb{j}, \pmb{k}$$
 in \mathbb{R}^3 $\pmb{i} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$ $\pmb{j} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}$ $\pmb{k} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$

lacktriangle Every subspace of \mathbb{R}^n has an orthogonal basis.

Orthogonal Subspaces

▶ Subspace **S** is orthogonal to subspace **T**: Every vector in **S** is orthogonal to every vector in **T**.

Orthogonal Subspaces

▶ The row space $C(A^{\top})$ is orthogonal to the nullspace N(A).

$$A oldsymbol{x} = egin{bmatrix} \mathsf{row} \ 1 \ dots \ \mathsf{row} \ m \end{bmatrix} egin{bmatrix} oldsymbol{x} \end{bmatrix} = egin{bmatrix} 0 \ dots \ 0 \end{bmatrix}$$

▶ The column space C(A) is orthogonal to the left nullspace $N(A^{\top})$.

$$A^{\top} \boldsymbol{y} = \begin{bmatrix} (\mathsf{column} \ 1)^{\top} \\ \vdots \\ (\mathsf{column} \ m)^{\top} \end{bmatrix} \begin{bmatrix} \boldsymbol{y} \\ \end{bmatrix} = \begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix}$$

Orthogonal Subspaces

lacktriangle Every vector $oldsymbol{v}$ in \mathbb{R}^n has a row space component $oldsymbol{v}_{row}$ and a nullspace component $oldsymbol{v}_{null}$: $oldsymbol{v} = oldsymbol{v}_{row} + oldsymbol{v}_{null}$

$$A\boldsymbol{x} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- ► The row space $\mathbf{C}(A^{\top})$ is the plane of all vectors $\beta_1 \mathbf{a}_1^* + \beta_2 \mathbf{a}_2^*$.
- ▶ The nullspace N(A) is the line through u = (0, 0, 1): all vectors $\beta_3 u$

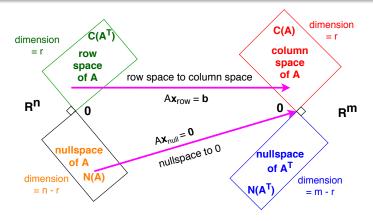

$$\boldsymbol{v} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} \in \mathbb{R}^3 \quad \boldsymbol{v} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \underbrace{\beta_1 \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} + \beta_2 \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}}_{\boldsymbol{v}_{row}} + \underbrace{\beta_3 \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}}_{\boldsymbol{v}_{null}}$$

- ▶ Dimensions: **dim** $C(A^{\top})$ + **dim** N(A) = r + (n r) = n.
- lacktriangle A row space basis $(r \ ext{vectors})$ and a nullspace basis $(n-r \ ext{vectors})$ produces a basis for the whole \mathbb{R}^n (n vectors).

The Big Picture

Fundamental Theorem in Linear Algebra

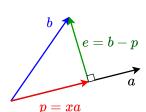

The row space and nullspace of A are orthogonal complements in \mathbb{R}^n .

Projection onto a Line

$$ightharpoonup e = b - p$$

$$ightharpoonup p = xa$$

ightharpoonup Because e is orthogonal to a:

$$\mathbf{a}^{\top} \mathbf{e} = 0$$

$$\mathbf{a}^{\top} (\mathbf{b} - \mathbf{p}) = 0$$

$$\mathbf{a}^{\top} (\mathbf{b} - x\mathbf{a}) = 0$$

$$x\mathbf{a}^{\top} \mathbf{a} = \mathbf{a}^{\top} \mathbf{b}$$

$$x = \frac{\mathbf{a}^{\top} \mathbf{b}}{\mathbf{a}^{\top} \mathbf{a}}$$

- lacksquare Therefore, $oldsymbol{p}=oldsymbol{a}x=oldsymbol{a}rac{oldsymbol{a}^{ op}oldsymbol{b}}{oldsymbol{a}^{ op}oldsymbol{a}}$
- ▶ There is a projection matrix P that p = Pb.

Projection onto a Line

$$P = \frac{aa^{\top}}{a^{\top}a}$$

- ▶ Column space of A: matrix-vector multiplication $Ax \in \mathbf{C}(A)$.
- ▶ p = Pb. What is the column space C(P)?
- $ightharpoonup \mathbf{C}(P)$ is the line through a.
- ▶ Is *P* symmetric?

$$P^{ op} = \left(rac{aa^{ op}}{a^{ op}a}
ight)^{ op} = rac{aa^{ op}}{a^{ op}a} = P.$$
 Yes.

What if we project b twice?

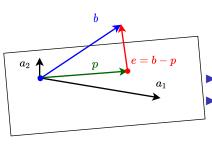

$$P^2 = \left(\frac{\boldsymbol{a}\boldsymbol{a}^\top}{\boldsymbol{a}^\top\boldsymbol{a}}\right)\left(\frac{\boldsymbol{a}\boldsymbol{a}^\top}{\boldsymbol{a}^\top\boldsymbol{a}}\right) = \frac{\boldsymbol{a}\boldsymbol{a}^\top}{\boldsymbol{a}^\top\boldsymbol{a}} = P$$

- ► Why bother with projection?
- ▶ Because Ax = b may have no solution $(m \gg n)$. b might not in the column space C(A).
- ▶ Solve $A\hat{x} = p$ instead, where p is the projection of b onto the column space $\mathbf{C}(A)$.

$$A = \begin{bmatrix} | & | \\ \boldsymbol{a}_1 & \boldsymbol{a}_2 \\ | & | \end{bmatrix}$$

- ▶ Plane of a_1 , a_2 = Column space of A.
- **p** is a linear combination of a_1, a_2 .

$$p = \hat{x}_1 \mathbf{a}_1 + \hat{x}_2 \mathbf{a}_2$$
$$= A\hat{\mathbf{x}}$$

Find $\hat{m{x}}$.

- $p = A\hat{x}$. Find \hat{x} .
- ightharpoonup e = b p is perpendicular to the plane.

$$\begin{bmatrix} \mathbf{a}_{1}^{\top} \\ \mathbf{a}_{2}^{\top} \end{bmatrix} \begin{bmatrix} \mathbf{e} \\ \mathbf{e} \\ \mathbf{d} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$A^{\top} \mathbf{e} = \mathbf{0}$$

$$A^{\top} (b - A\hat{\mathbf{x}}) = \mathbf{0}$$

$$A^{\top} A\hat{\mathbf{x}} = A^{\top} \mathbf{b}$$

$$\hat{\mathbf{x}} = (A^{\top} A)^{-1} A^{\top} \mathbf{b}$$

- We have $\boldsymbol{p} = A\hat{\boldsymbol{x}} = A(A^{\top}A)^{-1}A^{\top}\boldsymbol{b}$.
- ► The projection matrix *P*:

$$P = A(A^{\top}A)^{-1}A^{\top}$$

▶ Is *P* symmetric?

$$P^{\top} = (A(A^{\top}A)^{-1}A^{\top})^{\top} = A((A^{\top}A)^{-1})^{\top}A^{\top}$$
$$= A((A^{\top}A)^{\top})^{-1}A^{\top}$$
$$= A(A^{\top}A)^{-1}A^{\top} = P$$

Yes.

▶ Is $P^2 = P$?

$$P^{2} = A(A^{\top}A)^{-1}A^{\top}A(A^{\top}A)^{-1}A^{\top}$$

$$= A(A^{\top}A)^{-1}(A^{\top}A)(A^{\top}A)^{-1}A^{\top}$$

$$= A(A^{\top}A)^{-1}A^{\top} = P$$

Q with Orthonormal Columns

$$\begin{aligned} Q_1 &= \frac{1}{3} \begin{bmatrix} 2\\2\\-1 \end{bmatrix} & Q_1^\top Q_1 = \begin{bmatrix} 1 \end{bmatrix} \\ Q_2 &= \frac{1}{3} \begin{bmatrix} 2&2\\2&-1\\-1&2 \end{bmatrix} & Q_2^\top Q_2 = \begin{bmatrix} 1&0\\0&1 \end{bmatrix} \\ Q_3 &= \frac{1}{3} \begin{bmatrix} 2&2&-1\\2&-1&2\\-1&2&2 \end{bmatrix} & Q_3^\top Q_3 = \begin{bmatrix} 1&0&0\\0&1&0\\0&0&1 \end{bmatrix} \end{aligned}$$

- Columns of Q's are orthonormal.
- ▶ Each one of those matrices has $Q^TQ = I$.
- $ightharpoonup Q^{\top}$ is a left inverse of Q.
- $ightharpoonup Q_3Q_3^{\top}=I.\ Q_3^{\top}$ is also a right inverse.

▶ All the matrices $P = QQ^{\top}$ have $P^T = P$.

$$P^{\top} = (QQ^{\top})^{\top} = QQ^{\top} = P$$

▶ All the matrices $P = QQ^{\top}$ have $P^2 = P$.

$$P^2 = (QQ^\top)(QQ^\top) = Q(Q^\top Q)Q^\top = QQ^\top = P$$

P is a projection matrix.

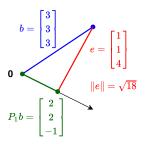

Orthogonal Projection

If $P^2 = P = P^{\top}$ then $P \boldsymbol{b}$ is the orthogonal projection of \boldsymbol{b} onto the column space of P.

▶ Project $\boldsymbol{b} = (3,3,3)$ on the Q_1 line. $P_1 = Q_1Q_1^{\top}$

$$P_1 \boldsymbol{b} = \frac{1}{9} \begin{bmatrix} 2 \\ 2 \\ -1 \end{bmatrix} \begin{bmatrix} 2 & 2 & -1 \end{bmatrix} \begin{bmatrix} 3 \\ 3 \\ 3 \end{bmatrix} = \frac{1}{9} \begin{bmatrix} 2 \\ 2 \\ -1 \end{bmatrix} 9 = \begin{bmatrix} 2 \\ 2 \\ -1 \end{bmatrix}$$

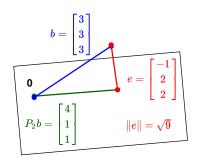

▶ P_1 splits \boldsymbol{b} in 2 perpendicular parts: projection $P_1\boldsymbol{b}$ and error $\boldsymbol{e} = \boldsymbol{b} - P_1\boldsymbol{b}$

▶ Project $\boldsymbol{b} = (3,3,3)$ on the Q_2 plane. $P_2 = Q_2 Q_2^{\top}$

$$P_{2}\boldsymbol{b} = \frac{1}{9} \begin{bmatrix} 2 & 2 \\ 2 & -1 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} 2 & 2 & -1 \\ 2 & -1 & 2 \end{bmatrix} \begin{bmatrix} 3 \\ 3 \\ 3 \end{bmatrix} = \frac{1}{9} \begin{bmatrix} 2 & 2 \\ 2 & -1 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} 9 \\ 9 \end{bmatrix} = \begin{bmatrix} 4 \\ 1 \\ 1 \end{bmatrix}$$

- $ightharpoonup P_2$ projects **b** on the column space of Q_2 .
- ▶ The error vector $b P_2b$ is shorter than $b P_1b$.

$$Q_3 = \frac{1}{3} \begin{bmatrix} 2 & 2 & -1 \\ 2 & -1 & 2 \\ -1 & 2 & 2 \end{bmatrix}$$

- $\blacktriangleright \text{ What is } P_3 \boldsymbol{b} = Q_3 Q_3^\top \boldsymbol{b} ?$
- ▶ Project b onto the whole space \mathbb{R}^3 .
- $ightharpoonup P_3 = Q_3Q_3^{ op} = I$. Thus, $P_3 {m b} = {m b}$. Vector ${m b}$ is in \mathbb{R}^3 already.
- ► The error e is zero!!!

Orthogonalization

Determine if a list of vectors a_1, a_2, \ldots, a_k is linearly independent.

Gram-Smidth algorithm

given vectors a_1, a_2, \dots, a_k for $i = 1, \dots, k$

- $oldsymbol{0}$ Orthogonalization. $ilde{m{q}}_i = m{a}_i (m{q}_1^\mathsf{T}m{a}_i)m{q}_1 \ldots (m{q}_{i-1}^\mathsf{T}m{a}_i)m{q}_{i-1}$
- ② Test for linear dependence. If $\tilde{\boldsymbol{q}}_i=0$, quit.
- **3** Normalization. $oldsymbol{q}_i = ilde{oldsymbol{q}}_i/\| ilde{oldsymbol{q}}_i\|$
- If the vectors are linearly independent, the Gram-Smidth algorithm produces an orthonormal collection of vectors q_1, \ldots, q_k .
- If the vectors a_1, \ldots, a_{j-1} are linearly independent, but a_1, \ldots, a_j are linearly dependent, the algorithm detects this and terminates.

Orthogonalization: Example

$$a_1 = (-1, 1, -1, 1), \quad a_2 = (-1, 3, -1, 3), \quad a_3 = (1, 3, 5, 7)$$

Applying the Gram-Smidth algorithm gives the following results.

i = 1:

$$\tilde{q}_1 = a_1$$

$$q_1 = \frac{1}{\|\tilde{q}_1\|} \tilde{q}_1 = (-1/2, 1/2, -1/2, 1/2)$$

i = 2:

$$\begin{split} \tilde{\boldsymbol{q}}_2 &= \boldsymbol{a}_2 - (\boldsymbol{q}_1^\mathsf{T} \boldsymbol{a}_2) \boldsymbol{q}_1 \\ &= (-1, 3, -1, 3) - 4(-1/2, 1/2, -1/2, 1/2) = (1, 1, 1, 1) \\ \boldsymbol{q}_2 &= \frac{1}{\|\tilde{\boldsymbol{a}}_2\|} \tilde{\boldsymbol{q}}_2 = (1/2, 1/2, 1/2, 1/2) \end{split}$$

Orthogonalization: Example

i = 3:

$$\begin{split} \tilde{\boldsymbol{q}}_3 &= \boldsymbol{a}_3 - (\boldsymbol{q}_1^\mathsf{T} \boldsymbol{a}_3) \boldsymbol{q}_1 - (\boldsymbol{q}_2^\mathsf{T} \boldsymbol{a}_3) \boldsymbol{q}_2 \\ &= \begin{bmatrix} 1 \\ 3 \\ 5 \\ 7 \end{bmatrix} - 2 \begin{bmatrix} -1/2 \\ 1/2 \\ -1/2 \\ 1/2 \end{bmatrix} - 8 \begin{bmatrix} 1/2 \\ 1/2 \\ 1/2 \\ 1/2 \end{bmatrix} = \begin{bmatrix} -2 \\ -2 \\ 2 \\ 2 \end{bmatrix} \\ \boldsymbol{q}_3 &= \frac{1}{\|\tilde{\boldsymbol{q}}_3\|} \tilde{\boldsymbol{q}}_3 = (-1/2, -1/2, 1/2, 1/2) \end{split}$$

▶ The completion of the Gram-Smidth algorithm without early termination indicates that the vectors a_1, a_2, a_3 are linearly independent.

QR factorization: A = QR

$$A = QR$$

$$\begin{bmatrix} | & | & & | \\ \mathbf{a}_1 & \mathbf{a}_2 & \dots & \mathbf{a}_n \\ | & | & & | \end{bmatrix} = \begin{bmatrix} | & | & & | \\ \mathbf{q}_1 & \mathbf{q}_2 & \dots & \mathbf{q}_n \\ | & | & & & | \end{bmatrix} \begin{bmatrix} r_{11} & r_{12} & \dots & r_{1n} \\ 0 & r_{22} & \dots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & r_{nn} \end{bmatrix}$$

$$r_{kk} = \|\tilde{\mathbf{q}}_k\|$$

$$r_{k-1,k} = \mathbf{q}_{k-1}^\mathsf{T} \mathbf{a}_k$$

QR factorization: A = QR

$$\begin{split} \hat{\boldsymbol{x}} &= (A^\mathsf{T} A)^{-1} A^\mathsf{T} \boldsymbol{b} \\ &= ((QR)^\mathsf{T} (QR))^{-1} (QR)^\mathsf{T} \boldsymbol{b} \\ &= (R^\mathsf{T} Q^\mathsf{T} QR)^{-1} R^\mathsf{T} Q^\mathsf{T} \boldsymbol{b} \\ &= (R^\mathsf{T} R)^{-1} R^\mathsf{T} Q^\mathsf{T} \boldsymbol{b} \qquad \text{(because } Q^\mathsf{T} Q = I) \\ &= R^{-1} R^{-\mathsf{T}} R^\mathsf{T} Q^\mathsf{T} \boldsymbol{b} \\ &= R^{-1} Q^\mathsf{T} \boldsymbol{b} \end{split}$$

Solving for \hat{x} by solving $R\hat{x} = Q^{\mathsf{T}}b$ with back-substitution.
